## Definition

A linear list is a finite, ordered sequence of data items known as elements. "Ordered" in this definition means that each element has a position in the list.

### Comparison of implementations

### Iteration on list

Why?

Implementation in C++

## General list:

- No restrictions on which operation can be used on the list.
- No restrictions on where data can be inserted/deleted.
- **Unsorted list**: data are not arranged in particular order.
- **Sorted list**: data are arranged according to a key.

## Linear list concepts

List ADT

### Singly linked list

Conceptual idea

Implementation in C++

### Comparison of implementations

### Iteration on list

Why?

Implementation in C++

## Restricted list:

- Only some operations can be used on the list.
- Data can be inserted/deleted only at the ends of the list.
- **Queue**: FIFO (First-In-First-Out).
- **Stack**: LIFO (Last-In-First-Out).

Implementation in C++

## Definition

A list of elements of type  $T$  is a finite, ordered sequence of elements of  $T$ .

## Basic concepts:

- A list is **empty** when it contains no elements.
- The number of elements currently stored is called the **length (size)** of the list.
- The beginning of the list is called the **head**, the end of the list is called the **tail**.

## Basic operations:

- Construct a list, leaving it empty.
- Insert an element.
- Remove an element.
- Search an element.
- Retrieve an element.
- Traverse the list, performing a given operation on each element.

## Linear list concepts

### List ADT

## Array implementation

How to store?

Implementation in C++

## Singly linked list

Conceptual idea

Implementation in C++

## Comparison of implementations

## Iteration on list

Why?

Implementation in C++

## Extended operations:

- Determine whether the list is **empty** or not.
- Determine whether the list is **full** or not.
- Find the **size** of the list.
- **Clear** the list to make it empty.
- **Replace** an element with another element.
- **Merge** two ordered list.
- **Append** an unordered list to another.

# List ADT: Implementation in C++

```
template <class T>
class IList
{
public:
    virtual void add(T e) = 0;
    virtual void add(int index, T e) = 0;
    virtual T removeAt(int index) = 0;
    virtual bool removeItem(T item) = 0;
    virtual bool empty() = 0;
    virtual int size() = 0;
    virtual void clear() = 0;
    virtual T get(int index) = 0;
    virtual void set(int index, T e) = 0;
    virtual int indexOf(T item) = 0;
    virtual bool contains(T item) = 0;
    virtual string toString() = 0;
};
```

# Contiguous Implementation of List

In processing a contiguous list with  $n$  elements:

- **Insert** and **Remove** operate in time approximately proportional to  $n$  (**require physical shifting**).
- **Clear**, **Empty**, **Full**, **Size**, **Replace**, and **Retrieve** in constant time.

# Nodes

The elements in a linked list are called **nodes**.

A **node** in a linked list is a structure that has at least two fields:

- the data,
- the address of the next node.

A node with  
one data field

A node with  
three data fields

A node with one  
structured data field

## Arrays: Pros and Cons

- **Pros:** Access to an array element is fast since we can compute its location quickly.
- **Cons:**
  - If we want to insert or delete an element, we have to shift subsequent elements which slows our computation down.
  - We need a large enough block of memory to hold our array.

## Linked Lists: Pros and Cons

- **Pros:** Inserting and deleting data does not require us to move/shift subsequent data elements.
- **Cons:** If we want to access a specific element, we need to traverse the list from the head of the list to find it which can take longer than an array access.

# Comparison of implementations of list

- **Contiguous storage is generally preferable when:**
  - the entries are individually very small;
  - the size of the list is known when the program is written;
  - few insertions or deletions need to be made except at the end of the list; and
  - random access is important.
- **Linked storage proves superior when:**
  - the entries are large;
  - the size of the list is not known in advance; and
  - flexibility is needed in inserting, deleting, and rearranging the entries.

# Why iteration?

## Problem on iteration

Consider a problem that you have to travel all elements in list and make change some elements like increasing elements with odd data (on integer lists).

## Comparison on implementations

If only use operation GET on list:

- With array implementation:  $O(n)$
- With linked list:  $O(n^2)$

# Definition

## Iterator: Definition

Some operations on lists, most critically those to insert and remove from the middle of the list, require the notion of a position.

**Iterators** are used to point at the memory addresses of nodes in list.

$$v[k] == *(v.begin()+k)$$

**Figure:** Iterator and usage

# Implementation in C++

```
class IntSLinkedList : public IList<int> {  
    // ...  
public:  
    class Iterator {  
        Node *pNode;  
        IntSLinkedList* pList;  
  
    public:  
        Iterator(IntSLinkedList* pList = NULL,  
                 bool begin = true);  
        Iterator& operator=(const Iterator&  
                             iterator);  
        T& operator*();  
        bool operator!=(const Iterator& iterator);  
        void remove();  
        void set(int element);  
        Iterator& operator++();  
        Iterator operator++(int);  
    };  
};
```
